## Author Note

- Availability Statement: All data, coding and analysis scripts are publicly available via
- 6 the Open Science Framework repository. The preregistration can be accessed here. Conflict
- <sub>7</sub> of Interest Disclosure: There were no conflicts of interest in relation to the authorship or
- $_{\rm 8}$   $\,$  publication of this article. Ethics Approval Statement: The study was approved by the
- 9 UNSW Human Research Ethics Advisory Panel prior to data collection. Acknowledgements:
- The authors would like to acknowledge the tremendous efforts of the coding team. Each
- $_{11}$  member of the coding team played an integral role in this investigation; their assistance is
- truly appreciated.

2

Abstract

Although open science has become a popular tool to combat the replication crisis, it is 14 unclear whether the uptake of open science practices has been consistent across the field of 15 psychology. In this study, we tested whether data and material sharing, two prominent open 16 science practices, differed as a function of psychological subfield at the distinguished journal, 17 Psychological Science. The results showed that open data and open materials scores 18 increased from 2014-2015 to 2019-2020. Of note, articles published in the field of 19 developmental psychology generated considerably lower open data and open materials scores, 20 compared to articles in other subfields. These findings are discussed in the context of why 21 developmental psychologists may be slower to adopt open science practices, compared to 22 other researchers, and how journals can more effectively encourage authors to practice open science across psychology. As part of our analyses, we also looked at how the awarding of Open Science Badges related to researchers' open science behaviours, showing that the shared data and materials were less usable expected, even for articles that earned badges. We propose an alternative open science initiative, that may be more effective in increasing the replicability of psychological research.

29 Keywords: open data; open materials; subfield differences; developmental psychology

Are we all on the same page? Subfield differences in open science practices in psychology

The field of psychology, like many other scientific disciplines, is currently facing a replication crisis, in which researchers are struggling to replicate existing findings. In 2015, a group of 270 psychological researchers attempted to replicate the findings of 100 psychology experiments. Whilst 97% of the original studies generated statistically significant findings, only 36% of the replication attempts were statistically significant. In addition, the replicated effects were, on average, half the size of the original effects (Open Science Collaboration, 2015). These findings illustrate the poor replicability of psychological research and the pressing need to rectify flawed research practices.

Open science practices, which increase the transparency of, and access to, scientific research, have been used to combat the replication crisis within psychology. (Klein et al., 2018). Open data and open materials practices, for example, involve researchers sharing their raw data and experimental materials on publicly accessible online repositories. These practices are designed to make it easier for others to replicate the methodology and reproduce the results from published work (Klein et al., 2018).

To encourage researchers to employ open science practices, many psychology journals
have implemented incentives, like Open Science Badges. In 2013, the Center for Open
Science established three Open Science Badges (Open Data, Open Materials and
Preregistered) to acknowledge and reward researchers for their use of open science practices
(Center for Open Science, 2021). The Open Data and Open Materials Badges, for example,
are awarded when the data and materials that are required to reproduce the methods and
results of a study are shared publicly online. To date, over 75 journals (40 in Psychology)
have adopted Open Science Badges (Center for Open Science, 2021).

At *Psychological Science*, the Association of Psychological Science's flagship journal,

Open Science Badges appear to have been successful in encouraging researchers to adopt

open science practices. In 2016, Kidwell et al. coded the frequency of data and material sharing in the 18 months before and after Open Science Badges were implemented at *Psychological Science*. Kidwell et al. found that data sharing increased dramatically from 2.5% of articles prior to badges to 39.4% of articles following badges. Materials sharing also rose from 12.7% to 30.3%. Data and material sharing in control journals, such as the *Journal of Personality and Social Psychology*, which did not award badges, remained low over the same time period (Kidwell et al., 2016). Although their study simply described the proportion of articles that engaged in data and materials sharing before and after the policy change, the results led Kidwell et al. to conclude that Open Science Badges successfully incentivised the uptake of open science practices at *Psychological Science*.

The support for open science continues to grow, however, it is not yet clear whether 66 engagement with open science is consistent across different fields within psychology. Notably, 67 the field of developmental psychology has received significant criticism for its lack of 68 receptivity towards open science. As Figure 1 illustrates, prominent developmental 69 researchers, Prof Michael Frank and Dr. Jennifer Pfeifer, have labelled the Society for 70 Research in Child Development's (SRCD) open science policy as 'weak' and as one that 71 undervalues openness.'(Frank, 2020, March 6; Pfeifer, 2020, March 8). More recently, the Editor-in-Chief of Infant and Child Development, Prof Moin Syed, stated that the uptake of 73 open science within the field of developmental psychology has been 'slow and uneven' (Syed, 2021). A survey supporting these viewpoints showed that 80% of researchers publishing in Child Development felt their institutions failed to provide adequate guidance or financial support for sharing data (SRCD Task Force on Scientific Integrity and Openness Survey (2017), cited in Gennetian et al., (2020)). Developmental psychology researchers may be slower to adopt open science practices than those in other psychological disciplines, however, this possibility has yet to be empirically investigated.

Using meta-research, the study of research itself, we can empirically assess whether

81

Figure 1. Twitter thread about Society for Child Development open science policy.

developmental psychology is truly behind in the open science movement. Previous investigations, including Kidwell et al. (2016), have revealed that open science incentives can increase the use of open science practices. However, it is unclear whether Open Science Badges, have had the same impact across different psychological subfields and whether the effect is sustained over time. To address this research question, we used the open data from the Kidwell et al., (2016) study and designed a quantitative scoring system to examine whether rates of data and material sharing, following the implementation of Open Science Badges at *Psychological Science*, differed as a function of subfield. In addition, we applied the same coding system to articles published in the most recent 18 months (Jul 2019-Dec 2020) to test whether the badges have continued to be impactful and whether the impact has been consistent across subfields. We were particularly interested in determining whether developmental psychology researchers publishing in *Psychological Science* engaged with open

science practices at the same rate as researchers from other subdomains of psychology. Our methods and analysis plan were preregistered at the Open Science Framework.

96 Methods

## 97 Design

This study had a quasi-experimental design; all articles were systematically assigned to one of seven subfields. For each article, we used coded variables to compute two scores that indexed the transparency of data and materials, respectively. Changes in data and material sharing were analysed over six-month intervals.

# 102 Sample

The Kidwell et al., (2016) sample included all Psychological Science articles published 103 between January 2014 and May 2015 (N = 367), which were coded to evaluate the openness 104 of their data and materials. To identify how data and material sharing may have changed 105 since 2014-2015, our sample also included all Psychological Science articles that were 106 published between July 2019 and December 2020 (N = 242). Non-empirical articles that did 107 not contain an experiment or analysis, including editorials, commentaries, replies, corrigenda, 108 errata and retractions, were excluded from our analysis. After filtering out these 109 non-empirical articles from the sample, 322 articles published between 2014-2015 and 193 110 articles published between 2019-2020, remained. 111

#### 112 Materials

117

To assess the transparency of data and materials for each article, Kidwell et al. (2016)
employed a systematic coding system (Kidwell system and variable definitions). We
downloaded the Kidwell et al. data from their OSF repository and filtered the dataset to
only include *Psychological Science* articles published between January 2014 and May 2015.

In addition to the variables that Kidwell et al. had coded, we also coded for whether

the article specified their analysis software or not, and which type of analysis software had
been specified (e.g., R, JASP, SPSS etc). These variables were important to include because
when authors' identify analysis software, the analysis procedure can be easier to follow and
the chance of successfully reproducing the analysis may increase (National Academies of
Sciences, Medicine, & others, 2019). The same amended version of the Kidwell et al. coding
system, including the two additional analysis software variables, was used to code the articles
that were published between July 2019 and December 2020.

We designed an additional coding system (subfield system and variable definitions) to assign all the articles to one of seven psychological subfields: Developmental Psychology, Social Psychology, Cognition, Perception, Health Psychology, Cognitive Neuroscience and Behavioural Neuroscience. We identified these seven subfields as those that the majority of Psychological Science articles fall into, after thoroughly reviewing the journal website.

Prior to data collection, each member of the coding team coded five trial articles, to confirm their understanding of the coding process. These trial articles were *Psychological*Science articles originally coded by Mallory Kidwell, the primary investigator in the Kidwell et al. (2016) study. Kidwell's coding acted as the standard to which coders' responses were compared. The senior coder in the current study generated the standard for the variables that weren't included in the Kidwell et al. coding system (i.e. those related to software and subfield). The trial articles varied in the transparency of their data and materials, and therefore, exposed coders to a representative range of coding outcomes.

The coding team coded both the trial and target articles via a Qualtrics survey,
containing a series of multiple-choice questions. The questions were structured in an 'if-then'
manner, with some questions only being asked if coders provided particular answers to the
questions prior. For example, coders were only asked about the participants' age, if they had
specified that the participants in the study were 'Humans' as opposed to 'Animals.'

## **Procedure**

151

154

157

158

159

160

161

162

After the investigation had been approved by the Human Research Ethics Advisory 144 Panel, we assembled a team of volunteer coders, comprising of undergraduate psychology 145 students. Once the coders completed the five trial articles and the senior coder was confident that each coder understood how to code all the variables, the coders were provided access to the target set of articles to begin coding using the Qualtric survey. 148

Scoring procedure. After all articles had been coded, we imported the data from 149 Qualtrics into the software environment, R (R Core Team, 2020). For the articles that were 150 published between 2014-2015, we combined the newly collected data related to softwre and subfield with the data from Kidwell et al. (2016). Each article, across both the 2014-2015 152 and 2019-2020 datasets, was assigned to one of the seven psychological subfields and received 153 an open data and open materials score. The open data score indexed the extent to which the data were transparent, whilst the open materials score indexed the extent to which the 155 materials were transparent. To calculate the scores, we weighted each coded variable 156 according to how much it improved the transparency of the data and materials, respectively.

Table 1: Open data scoring (left) and open materials scoring (right) criteria

Variable	Score Assigned
Low-level transparency	
Presence of data availability statement	1
Data reported to be available	1
Analysis software specified	1
Medium-level transparency	
Presence of data URL	2
Data URL is functional	2
Data located at URL	2
Data are downloadable	2
Data correspond to article	2
Data are complete	2
High-level transparency	
Codebook available with data	5
Analysis scripts available with data	5

Variable	Score Assigned
Low-level transparency	
Presence of materials availability statement	1
Materials reported to be available	1
Medium-level transparency	
Presence of materials URL	2
Materials URL is functional	2
Materials located at URL	2
Materials are downloadable	2
Materials correspond to article	2
Materials are complete	2
High-level transparency	
Explanation of materials/corresponding scripts	5

There were three levels of transparency: low-level transparency variables received a value of 1, moderate-level transparency variables received a value of 2 and high-level transparency variables received a value of 5 (see Table 1). We summed these scores so that each article received an open data score out of a possible 25 and an open materials score out of a possible 19. Higher scores reflected a higher level of transparency.

The senior coder randomly selected 25 empirical articles from the 164 2014-2015 dataset (8\% of the empirical sample), ensuring that an equal number had been 165 coded by each coder (n = 5), and double-coded these software and subfield variable. Using 166 the 'kappa2' function from the 'irr' package in R (Gamer, Lemon, & Singh, 2019), we ran a 167 Cohen's Kappa reliability analysis for subfield assignment, which revealed that the coding 168 team had good reliability compared to the senior coder's standard, k = .605, according to 169 Fleiss's (1981) guidelines. The percent agreement rating between the standard and the 170 coding team was 72%. Upon examining cases where the standard and the coding team 171 disagreed on an article's subfield assignment, we found that the discrepancy could usually be 172 attributed to the subject matter spanning across multiple subfields. Since our coding system 173 did not account for the possibility of a study belonging to multiple subfields, the results from our reliability analysis may be conservative.

For the 2019-2020 sample of articles, the senior coder similarly selected 25 articles from
the empirical sample (13%) and double-coded these articles. To assess reliability, each article
received a total openness score, representing the sum of the open data and open materials
score. We used the 'icc' function from the 'irr' package in R to generate an intraclass
correlation coefficient (ICC) (Gamer, Lemon, & Singh, 2019). The 'tolerance' level was set at
five Total Openness points; where scores fell within a five-point range of each other, they
were considered to be equivalent.

The ICC analysis showed that the coding team had excellent reliability relative to the senior coder's standard, according to Cicchetti's (1994) guidelines, ICC = .905, 95% CI (.772, .962). As a secondary measure of inter-rater reliability, we also calculated the percent agreement between the standard and coders' responses. The agreement rating between the coders and the standard was 73.7%, with a tolerance level of five Total Openness points.

Data analysis. We used R [Version 4.0.3; R Core Team (2020)] and the R-packages 188 afex [Version 1.0.1; Singmann, Bolker, Westfall, Aust, and Ben-Shachar (2021)], apa [Version 189 0.3.3; Gromer (2020); Aust and Barth (2020)], dplyr [Version 1.0.7; Wickham, François, 190 Henry, and Müller (2021), forcats [Version 0.5.1; Wickham (2021a)], greasy [Version 0.1.3; 191 Carroll, Schep, and Sidi (2021), qqhalves [Version 0.1.1; Tiedemann (2020)], qqplot2 [Version 192 3.3.5; Wickham (2016)], qqsiqnif [Version 0.6.3; Constantin and Patil (2021)], qoodshirt 193 [Version 0.2.2; Gruer (2021)], here [Version 1.0.1; Müller (2020)], irr [Version 0.84.1; Gamer, 194 Lemon, and Singh (2019)], janitor [Version 2.1.0; Firke (2021)], kableExtra [Version 1.3.4; 195 Zhu (2021)], lme4 [Version 1.1.27.1; Bates, Mächler, Bolker, and Walker (2015)], Matrix 196 [Version 1.3.4; Bates and Maechler (2021)], papaja [Version 0.1.0.9997; Aust and Barth 197 (2020), patchwork [Version 1.1.1; Pedersen (2020)], purr [Version 0.3.4; Henry and 198 Wickham (2020)], readr [Version 2.0.1; Wickham and Hester (2021)], report [Version 0.3.5; Makowski, Ben-Shachar, Patil, and Lüdecke (2021)], scales [Version 1.1.1; Wickham and Seidel (2020), stringr [Version 1.4.0; Wickham (2019)], tibble [Version 3.1.4; Müller and Wickham (2021), tidyr [Version 1.1.3; Wickham (2021b)], and tidyverse [Version 1.3.1; 202 Wickham et al. (2019)] for all our analyses. 203

Confirmatory Analyses. Analysis of Variance (ANOVA) analyses were run to 204 investigate differences in open data and open materials scores, separately, across the 205 2014-2015 and 2019-2020 datasets. In each analysis, we tested for a main effect of time, 206 measured over three six-month intervals, and subfield. To ensure that there was a 207 comparable number of articles in each subfield group, we combined Cognitive Neuroscience, 208 Behavioural Neuroscience, Health Psychology and Perception into a single 'Other' category. 200 As a result, a total of four subfield groups were included in our analysis: Developmental 210 Psychology, Social Psychology, Cognition and Other. We report effect sizes in terms of 211 generalised eta squared (ges).

**Exploratory Analyses.** After data collection, we were also interested in the

213

distribution of scores and how the spread of scores might differ by subfield. To illustrate this
we generated two raincloud plots that illustrated the distribution of open data and open
materials scores across 2019-2020. Raincloud plots visualise the distribution of scores in a
dataset by showing the density of subjects at each level of the dependent measure (Allen,
Poggiali, Whitaker, Marshall, & Kievit, 2019). In our case, where the violin plot was wider,
the concentration of articles that received the corresponding open data or open materials
score, was greater.

We also wanted to learn how Open Science Badges related to researchers' data and

materials sharing practices. To generate two corresponding figures, we filtered the 2019-2020 222 dataset to only include the articles that had received an Open Data Badge and an Open 223 Materials Badge, respectively. We then plotted the percentage of these articles that met a 224 series of data and materials sharing criteria, described in the Results section below. 225 **Preregistration.** We preregistered our aims, hypotheses, design, and planned 226 analysis procedure for the study at the OSF. Whilst we attempted to follow each of the 227 proposed procedures as closely as possible, we made one notable modification, choosing not 228 to normalise the Open Data and Open Materials Scores (so that they were both out of 100). 229 Since our study was focussed on measuring subfield differences and changes over time, within 230 each type of score, rather than comparing the differences between the two scores, we 231 ultimately realised that normalising the scores was not necessary. All the materials, data and 232 analysis scripts from the study can be accessed via the OSF. 233

Results

221

We first used the open data from Kidwell et al., (2016) and analysed whether open data and open materials scores improved across the 2014-2015 period and differed by subfield. As illustrated in Figure 2A, during the period immediately following the badge policy change, open data scores were uniformly low across subfields, F(3,310) = 2.23, MSE = 41.51, p = .085,  $\hat{\eta}_G^2 = .021$ . Whilst open data scores increased over

time, F(2,310) = 11.29, MSE = 41.51, p < .001,  $\hat{\eta}_G^2 = .068$ , this improvement did not differ as a function of subfield F(6,310) = 1.57, MSE = 41.51, p = .157,  $\hat{\eta}_G^2 = .029$ .

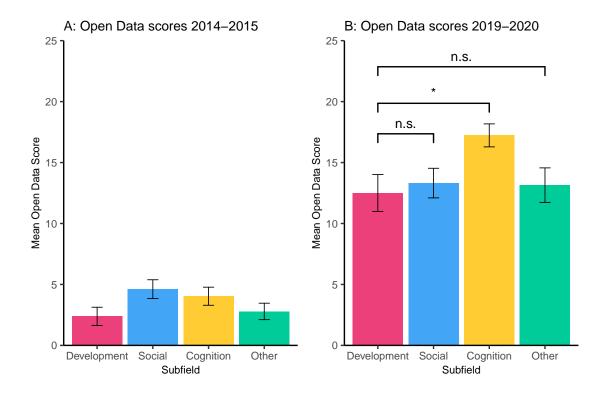

Figure 2. Mean open data scores for articles published in *Psychological Science* between 2014-2015 and 2019-2020 as a function of subfield.

Across the 2019-2020 period, open data scores also increased significantly, 242 F(2, 181) = 3.68, MSE = 70.92, p = .027,  $\hat{\eta}_G^2 = .039$ , and differed by subfield, 243  $F(3, 181) = 3.31, MSE = 70.92, p = .021, \hat{\eta}_G^2 = .052.$  When we compared the open data 244 scores from papers published in developmental psychology to each of the other subfield 245 categories (Figure 2B), we found that papers in developmental psychology had significantly lower open data scores (M = 12.50, SD = 8.83) than papers in cognition (M = 17.23, SD = 10.00(7.37), t(58.75) = -2.65, p = .010, but did not differ from papers published in social 248 psychology (M = 13.32, SD = 9.17), t(71.68) = -0.42, p = .675 or those that fell into the 249 other category (M = 13.15, SD = 9.07), t(71.12) = -0.31, p = .756. There was no 250 significant time by subfield interaction, F(6, 181) = 1.11, MSE = 70.92, p = .358,  $\hat{\eta}_G^2 = .035$ . 251

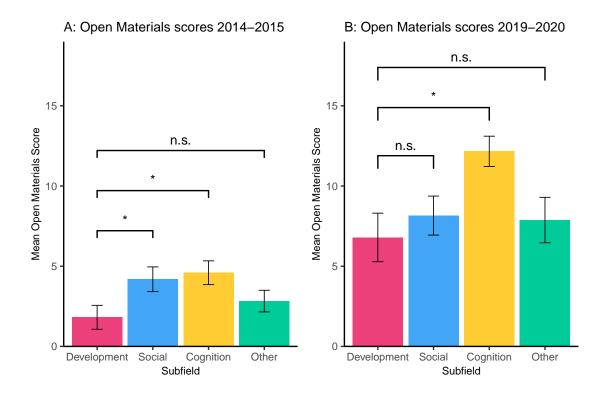

Figure 3. Mean open materials scores for articles published in *Psychological Science* between 2014-2015 and 2019-2020 as a function of subfield.

For open materials scores across 2014-2015, there were significant main effects of both 252 subfield, F(3,310) = 4.03, MSE = 32.16, p = .008,  $\hat{\eta}_G^2 = .038$ , and time period, 253  $F(2,310)=4.74,\,MSE=32.16,\,p=.009,\,\hat{\eta}_G^2=.030$  (see Figure 3A). Papers in 254 developmental psychology had lower open materials scores ( $M=1.82,\,SD=6.02$ ) than 255 those in both social (M = 4.19, SD = 7.34), t(153.62) = -2.75, p = .007, and cognition <math>(M = 4.19, SD = 7.34), t(153.62) = -2.75, p = .007, and cognition <math>(M = 4.19, SD = 7.34), t(153.62) = -2.75, p = .007, and cognition <math>(M = 4.19, SD = 7.34), t(153.62) = -2.75, p = .007, and cognition <math>(M = 4.19, SD = 7.34), t(153.62) = -2.75, p = .007, and cognition <math>(M = 4.19, SD = 7.34), t(153.62) = -2.75, p = .007, and cognition <math>(M = 4.19, SD = 7.34), t(153.62) = -2.75, p = .007, and cognition <math>(M = 4.19, SD = 7.34), t(153.62) = -2.75, p = .007, and cognition <math>(M = 4.19, SD = 7.34), t(153.62) = -2.75, p = .007, and cognition <math>(M = 4.19, SD = 7.34), t(153.62) = -2.75, p = .007, and cognition <math>(M = 4.19, SD = 7.34), t(153.62) = -2.75, p = .007, and cognition <math>(M = 4.19, SD = 7.34), t(153.62) = -2.75, c(153.62), c256 = 4.59, SD = 7.07, t(153.74) = -3.20, p = .002, but developmental open materials scores 257 did not differ from papers allocated to the other subfield category (M = 2.83, SD = 5.84), 258 t(137.95) = -1.19, p = .236. The interaction between time period and subfield, 259  $F(6,310) = 0.85, MSE = 32.16, p = .530, \hat{\eta}_G^2 = .016, \text{ was not statistically significant.}$ 260

As illustrated in Figure 3B, there were also subfield differences in open materials scores during the 2019-2020 period, F(3, 181) = 5.24, MSE = 53.87, p = .002,  $\hat{\eta}_G^2 = .080$ .

Consistent with open data scores, papers published in developmental psychology had 263 significantly lower open materials scores (M = 6.79, SD = 8.83) than papers published in 264 cognition, (M = 6.79, SD = 8.83), t(61.36) = -3.45, p = .001, however, open materials265 scores did not differ between developmental and social psychology (M = 6.79, SD = 8.83), 266 t(68.36) = -0.84, p = .406, nor between developmental psychology and the other subfield 267 category (M = 6.79, SD = 8.83), t(70.45) = -0.62, p = .539. There were no changes in open 268 materials scores across the time period between mid-2019 and the end of 2020, 269 F(2, 181) = 0.37, MSE = 53.87, p = .694,  $\hat{\eta}_G^2 = .004$ , and differences in subfield did not vary 270 over time, F(6, 181) = 0.48, MSE = 53.87, p = .822,  $\hat{\eta}_G^2 = .016$ . 271

Figure 4. Mean open data and open materials scores for articles published in *Psychological Science* as a function of subfield and time period.

It is clear that since the introduction of Open Science Badges in 2014, papers published in *Psychological Science* have become more open over time and that most recently, developmental psychology has lagged behind some, but not all, subfields. To determine

whether the rate of improvement from 2014-2015 through 2019-2020 differed significantly by subfield, we combined the data across the two coded time periods and looked for subfield by time interactions in both open data and open materials scores. As illustrated in Figure 4, there was no evidence that the magnitude of improvement over time differed by subfield for either both open data scores F(3,507) = 2.28, MSE = 55.28, p = .078,  $\hat{\eta}_G^2 = .013$  or open materials scores F(3,507) = 2.07, MSE = 40.21, p = .103,  $\hat{\eta}_G^2 = .012$ .

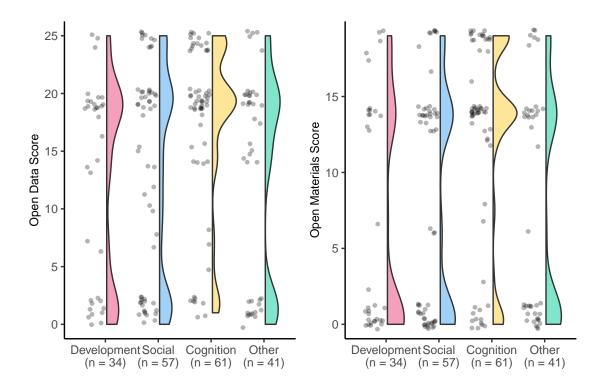

Figure 5. Distribution of open data and open materials scores earned by articles published in Psychological Science between 2019 and 2020 as a function of subfield

Our confirmatory analyses showed that on average, open data and materials scores for
papers published in *Psychological Science* have increased markedly across all subfields,
however, scores within each subfield varied widely. To explore changes in variability over
time, we used raincloud plots (Allen, Poggiali, Whitaker, Marshall, & Kievit, 2019) to
represent the distribution of open data and materials scores across subfields. Figure 5
illustrates that the majority of papers score on the upper half of the scale, however, there are

still one third of papers published that receive scores less than 5.

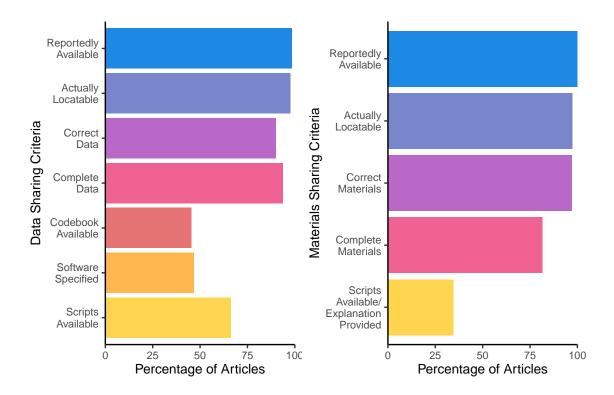

Figure 6. Proportion of articles published in Psychological Science in 2019-2020 that earned an Open Data Badge (left) or Open Materials Badge (right) and engaged with sharing criteria behaviours

We were surprised how few articles received very high open data and materials scores 288 even in 2019-2020. In order to receive very high scores, article authors needed to engage in 289 behaviours that make shared resources most useful (i.e. sharing data with a accompanying 290 codebook and analysis script). We were particularly interested in how common this kind of 291 metadata sharing was among papers that had earned an Open Data or Open Materials 292 Badge. To produce Figure 6, we filtered articles published within the 2019-2020 window for 293 those that were awarded open data and materials badges and then plotted the proportion of 294 those articles that shared codebooks and scripts along with complete data. 295

Figure 6 shows that the vast majority of papers earning an open data badge had

296

complete data available, however, less than half shared a codebook and only 66% included an analysis script. Similarly for open materials, most articles earning a badge shared raw materials on an open repository, but a relatively small percentage of articles also shared an script and/or detailed explanation of how to use the materials in a replication study.

301 Discussion

In the past few years, there has been concern from some academics that developmental psychology was lagging behind in its use of open science practices, compared to other psychological subfields. The results of the current study provide empirical support for this idea. Our analysis showed that since the introduction of Open Science Badges at Psychological Science in 2014, open science practices have generally improved, however, developmental psychology articles coded most recently had significantly lower open data and open materials scores relative to cognition articles.

There are several factors that may be contributing to lower open data and open 309 materials scores in developmental psychology. Notably, practicing open science may pose a 310 greater reputational risk to developmental scientists compared to researchers from other 311 subdisciplines (Gilmore, Cole, Verma, Van Aken, & Worthman, 2020). Participants in 312 developmental research are temperamental and unpredictable, which makes it difficult for 313 researchers to stick to strict experimental protocols (Peterson, 2016). For example, if a child 314 is getting fussy, the experimenter may deviate from the experimental protocol and allow the 315 parent to complete the paradigm with them (Slaughter & Suddendorf, 2007). These 316 "off-protocol" decisions make protocols difficult to replicate and add noise to experimental data (Peterson, 2016). Researchers may be reluctant to share data and materials online, out 318 of fear that they will be criticised for a lack of scientific rigor, and that their reputation may be harmed (Gilmore, Cole, Verma, Van Aken, & Worthman, 2020). It is possible that the 320 perceived risks of data and material sharing in developmental psychology may impact 321 openness and transparency 322

The scarcity of data in developmental psychology may further impede data sharing. 323 Developmental scientists usually recruit their participants from off-campus locations 324 (Peterson, 2016) making recruitment a time consuming and expensive process and sample 325 sizes generally small (Davis-Kean & Ellis, 2019). In contrast, cognition researchers are 326 typically able to recruit large samples of participants on campus or from online platforms 327 (Benjamin, 2019). According to the law of supply and demand, rare commodities are more 328 highly valued (Steuart, 1767). Given that willingness to share decreases as the value of an 320 item increases (Hellwig, Morhart, Girardin, & Hauser, 2015) it is possible that 330 developmental researchers are less likely to share data simply because it is more highly 331 valued than data in other subfields. 332

Finally, the methods that developmental psychologists use may make it particularly 333 difficult to share materials openly. As Peterson (2016) reports, in developmental studies, 334 experimental stimuli are typically constructed by hand and are set up manually by research 335 assistants. The physical nature of these experimental paradigms may make them more 336 difficult, and sometimes impossible, to share online. In contrast, computer-based 337 experimental paradigms are becoming increasingly popular in cognition and social 338 psychology. These paradigms, which can be automated and run online, make it relatively 339 easy to upload materials to online repositories (Paxton & Tullett, 2019). Subfield differences 340 in the types of materials researchers employ may explain why developmental psychologists 341 are less likely to share materials than researchers in other subfields. 342

Although developmental psychology appears to be lagging behind other subfields, there
is cause for optimism. Open data and materials scores for developmental psychology articles
published in *Psychological Science* improved from 2014 to 2020 at the same rate as articles in
other subfields. It seems that developmental psychology researchers, at least those who are
looking to publish in *Psychological Science*, are keeping up with their colleagues and
becoming more and more likely to adopt open data and open materials into their research

workflow.

It is clear that open data and materials practices are becoming more common, however, 350 the current findings highlight the significant progress that has yet to be made in the open 351 science movement across the field of psychology. We were surprised to see that in 2019-2020 352 a large proportion of articles received extremely low scores open data and open materials 353 scores. In addition, very few articles were awarded the highest possible open data and open 354 materials score, indicating that even when data and materials were shared, they were often 355 not accompanied by a codebook, analysis script and/or explanation of the materials. Roche et al. (2015) suggest that without these metadata, open data and open materials may be not be usable, both for the purpose of reproducing the findings of a particular study and conducting novel research. Like all open science incentives, Open Science Badges are not an 359 end to themselves; although the aim is to increase the transparency of research methods, the 360 ultimate goal is to improve the replicability. Whilst Open Science Badges appear to 361 incentivise researchers to share their data and materials, if they do not increase the 362 availability of metadata, then their value in overcoming the replication crisis, remains 363 debatable. 364

Our results also raise concerns about how well Open Science Badges criteria are 365 adhered to, in practice. According to the COS, Open Data Badges can only be awarded if a 366 'data dictionary' such as a codebook, or other related metadata is made available (Center for 367 Open Science, 2013a). Similarly, for articles to be awarded an Open Materials Badge, the 368 authors must provide a sufficiently detailed explanation of how the materials were used in the study, and how they can be reproduced, if they can't be shared digitally (Center for 370 Open Science, 2013b). We found that only 45% of the articles that were awarded an Open Data Badge in 2019-2020, shared a codebook, and only 35% of those awarded an Open 372 Materials Badge provided an explanation of their materials. These results not only suggest 373 that a very small proportion of the articles that received an Open Data and/or Open

Materials Badge were truly deserving of one, but they also show that the criteria for Open
Science Badges may be applied inconsistently. Further research is required to identify
whether this issue is specific to *Psychological Science*, or if it is a broader issue observed
across all journals that award Open Science Badges. In any case, the potentially inconsistent
application of the criteria for Open Science Badges questions how valid and reliable they are
as indicators of transparency and usability.

Where to from here? Open Science Badges have clearly had an impact on author 381 behaviour at Psychological Science but that there is still work to do in making psychology a 382 truly open science. Psychological Science was ideally suited for our subfield comparison due to its broad publishing scope. However, because Psychological Science implemented Open Science Badges, and is one of psychology's top tier journals, publishing only a very small 385 subset of high quality and novel research articles, it is unclear whether the results from the 386 current study reflect the field of psychology as whole. Future meta-research should focus on 387 open science practices across a broader range of psychology journals to assess whether it is 388 the badges per se, or a broader shift in research workflow that has resulted in improved 389 transparency at Psychological Science. 390

Although Open Science Badges may encourage authors to be more transperant in their 391 research, it is possible that they are rewarding researchers for doing the bare minimum, and 392 not actually pushing the field toward a more replicable science. Perhaps journals should 393 consider employing an open science scoring system, instead. Such a system (see (Hartshorne 394 & Schachner, 2012; Yang, Youyou, & Uzzi, 2020) for related examples) would involve psychology journals awarding each article they publish a "Reproduciblity Score" that indexes the likelihood of the findings being successfully reproduced based on the transparency of the data and materials. To maximise objectivity and to minimise time costs, an automated 398 algorithm would generate the Reproducibility Score (Altmejd et al., 2019; Yang, Youyou, & 399 Uzzi, 2020). Future research should test whether, compared to Open Science Badges, scores may be a more precise and meaningful indicator of transparency and potential replicability.

To conclude, the present study provides support for the existence of subfield differences in the uptake of open science practices, across the field of psychology. Whilst the findings indicated that researchers' use of open science practices have increased since *Psychological Science* introduced Open Science Badges in 2014, there appears to be considerable progress yet to be made. Although Open Science Badges do not appear to be as valuable in overcoming the replication crisis as they seem, an open science scoring system may provide a promising alternative. Overall, we hope that the results of the study enhance the way open science is endorsed and applied across psychological subfields.
